

LGCX

LONGEVITY CASH

FOR THE LONG HORIZON

Assets move.

Participation carries forward.

A shared asset for participation
in the longevity economy.

SETTLEMENT / ACCESS / COORDINATION

Protocol Snapshot

Asset, network and participation

Field	Specification
Name / symbol	Longevity Cash / LGCX
Canonical network / standard	Base Mainnet / ERC-20
Published supply ceiling	1,000,000,000 LGCX; supply definitions and contract controls are addressed in Section 10.
Custody	User self-custody
Core roles	Settlement / Access / Coordination
Architecture	Asset / Network functions / Applications / Partner network

Canonical contract

0x85AF63B5a6c054A2672bc4EC08B9190D3bcE15AE

Development status · 6 September 2026

Passport is in preparation for a private pilot. Partner integrations, Checkout and settlement routes are development-roadmap functions. Portable provider credentials and independent verification are interoperability development targets. Function availability, capacity and service terms are specified through the relevant product releases and provider offers. [1, 2]

Risk notice. LGCX may lose all market value. A balance does not guarantee service availability, financial return or a medical benefit. Asset rights and participation risks are set out in Sections 16 and 18.

00 /

The Long Horizon

Time cannot be minted or recovered, yet it is the boundary ultimately consumed by every choice.

A longer horizon means more than an additional number of years. It means work worth continuing, people worth knowing and possibilities still open. Health and time shape how much of that life can be experienced.

The LGCX thesis begins with a practical expectation: economic activity around healthspan will extend across years, institutions and changing stages of life. Genomics, epigenetics, proteomics, advanced diagnostics, AI drug discovery and preventive care form part of this landscape. Its progress can take many scientific paths. Its participants still need ways to discover, access and return to useful services.

The difficulty is continuity. A person may enter through a scientific gathering, later use a digital service and eventually engage with a laboratory or clinic. Each encounter can be worthwhile, yet accounts, membership conditions and participation records often remain specific to the institution that created them. The next relationship starts again.

A shared economic layer

Longevity Cash is a self-custodied digital asset designed for an open network of independent longevity providers, applications and participants. Its purpose is to connect settlement, Access and coordination around a relationship that can continue beyond one purchase.

The asset supplies a common economic reference. Passport is being developed to organize relevant eligibility and verified participation. Providers retain control of their services and choose the conditions under which they recognize that relationship.

This is a network around healthspan, rather than a wager on a single explanation of aging. Its identity comes from a shared direction; its usefulness must come from experiences worth completing and relationships worth continuing.

From interest to participation

The first reason to enter is concrete: an event, content, a booking or a service that matters. A useful working balance may preserve eligibility for several opportunities. A record of genuine participation can make a later encounter easier to navigate. Together, these are intended to turn isolated activity into a more continuous relationship.

The relevant standard is fulfilled use. A network becomes meaningful when the next opportunity is useful enough for a participant to return voluntarily—and when another independent provider has a reason to recognize that participation.

The first use opens a door. The next use begins a network.

Longevity Cash

One asset. Two complementary forms of continuity.

LGCX is an ERC-20 crypto-asset on Base. It can be held, transferred and inspected through compatible wallets and public on-chain records. The network connects asset state with a separate participation record. [1, 3]

	Economic state	Participation state
Primary reference	LGCX balances and transfers	Passport participation records
What it carries	A user-controlled asset recognized under published rules	Entry date and completed activity
How it changes	Transfers and on-chain state	Verified activity and record lifecycle rules
Portability	Transfers between compatible wallets	Selective recognition by compatible providers

LGCX carries transferable economic state. Passport organizes verifiable participation state. Provider rules connect the two. Token transfers do not transfer participation history. A completed experience records activity, rather than automatically securing a future booking or payment.

Why a shared asset?

A provider-specific account can support one institution's relationship; a stablecoin can support payment. LGCX pursues a shared, independently held asset that several institutions can recognize without issuing separate balances or controlling participants' funds.

Where providers recognize the same asset condition, a participant can maintain one working balance rather than several isolated balances. Compatible applications can read that state while offering different experiences. The shared reference supports coordination; useful offers give it substance.

Stablecoins and shared credentials can support alternative designs. A native token is not technically necessary for every element of the experience. The case for LGCX is the combined usefulness of its network-specific recognition rules, available opportunities and voluntary working balances, after wallet friction, price exposure and integration costs are considered.

A network asset, not a single-provider program

LGCX is designed to complement independent services. Payment, event participation, member content and selected cross-provider recognition can form different entrances to the same network. Providers may adopt only the functions that improve their own service relationship.

The distinguishing combination is a transferable asset, attributable participation and cross-institutional recognition. Its durability depends on delivery, trusted relationships and repeated use, rather than an exclusive technical invention.

System Architecture

Shared state. Independent responsibilities.

LGCX has four connected layers: the asset, network functions, applications and independent providers. Economic state and participation state are complementary information domains within those layers; they are not two tokens or two blockchains.

Four-layer design. Connections represent state, rules and interfaces, not custody. Credential interoperability follows the development roadmap.

How the layers connect

The asset layer supplies balances, transfers and inspectable on-chain state. Network functions apply settlement, eligibility and coordination rules. Applications such as Passport and Checkout present those functions to users. Providers supply the actual events, content, capacity and services.

The architecture separates reading asset state from authorizing a payment, and separates both from proving that an experience occurred. A provider may accept LGCX payments, recognize an Access condition or verify a participation record without adopting every other function.

Portability with a defined scope

Asset portability follows the supported chain and wallet interfaces. Participation portability requires compatible record formats, an identifiable issuer, a valid subject relationship and a receiving provider willing to recognize the record. A reservation remains tied to its specific offer and terms; recognizing its existence does not transfer its capacity to another provider.

Passport is an important interface, not a mandatory owner of the whole relationship. Interoperability development is directed toward records and verification methods that compatible applications can use without relying on a single presentation layer. Provider independence and participant control remain design requirements throughout that progression.

The Utility Layer

Settlement, Access and coordination

Settlement is the movement of an asset to meet a payment obligation through a supported route. **LGCX Access**, or **Access**, is provider-defined, verifiable eligibility for an event, content, booking or service under published conditions. **Coordination** is the use of a common asset and compatible rules to organize participation, provider recognition and appropriate ecosystem activity.

Function	Practical role
Settlement	Connect a payment to an identifiable purchase or booking.
Access	Evaluate a stated condition for a specific opportunity, with capacity and price visible.
Coordination	Align recognition rules and interfaces; support accountable ecosystem funding and, as governance matures, defined collective decisions.

The common asset can support several opportunities at once. Participation history can supply a separate, relevant qualification. Neither needs to stand in for the other: asset-based eligibility concerns current conditions, while a completion record concerns a past activity.

Coordination has three scopes. **Operational coordination** covers recognition and verification between providers. **Economic coordination** covers integration incentives, working balances and liquidity arrangements where useful. **Collective coordination** covers public goods and expressly defined governance functions. Coordination does not itself create a right to vote or receive revenue.

04 / The First Entry

The entry experience begins with something identifiable and worthwhile. A scientific gathering provides a simple design example: an organizer publishes the subject, time, capacity, eligibility, price and cancellation terms before a participant needs to acquire LGCX.

01 Discover	02 Qualify	03 Reserve	04 Participate	05 Record
-----------------------	----------------------	----------------------	--------------------------	---------------------

Passport's intended flow verifies the stated conditions, supports reservation where capacity remains and presents a short-lived, one-time QR Ticket for check-in. Verified completion can then create an attributable record. A later provider may recognize that record under a compatible offer.

A participant needs to understand three separate questions: **Am I eligible? Is a place reserved? Has any required payment been completed?** The interface must present each answer distinctly. Costs, gas requirements, conversion terms and support routes belong before commitment.

Early participation is meaningful through real experiences, feedback and a truthful starting date. The reason to remain is the next useful opportunity, not a promise that later participants will receive less.

Settlement & Merchant Model

Flexible settlement. Clear commitments.

The settlement design includes three development paths: direct, converted and split. Providers select supported routes according to their pricing, accounting and risk requirements; accepting LGCX need not mean retaining it.

Route	Provider receives	Operating purpose
Direct	LGCX	Retain the asset or maintain an operational balance.
Converted	An agreed stable asset or other asset	Use a supported conversion route with disclosed pricing, fees and execution conditions.
Split	A specified combination	Balance cash-flow requirements with a chosen LGCX position.

From quote to delivery

Checkout is designed to present the responsible provider, payment amount, network, total fees, quote expiry and any conversion terms before authorization. The user authorizes the payment separately from wallet sign-in. The application verifies settlement and reconciles it with the purchase or reservation.

Payment status and service status remain separate. A confirmed transfer establishes asset movement. Delivery depends on the provider fulfilling the offer. Partial payments, expired quotes, uncertain settlement and failed conversion require explicit handling and an accountable support route.

A provider may also accept conventional or stable-asset payment while recognizing an LGCX condition for a particular Access offer. This preserves payment choice and places the practical value of that condition in the opportunity itself.

Eligibility and confirmed reservations

Every offer must state its qualification checkpoint: application, reservation, redemption or another clearly defined time. A confirmed reservation identifies the capacity secured and the conditions that remain outstanding. Paying for an offer must not unexpectedly invalidate that same commitment merely because the payment reduced the wallet balance.

Later balance checks, expiry and cancellation conditions must be visible before reservation. Any preservation of eligibility must be explicit in the confirmed service record.

Refunds and reconciliation

The refund policy identifies the responsible party, unit of account, amount or calculation method, fees and timing. A refund can require a new transfer or a separate off-chain process. Price changes and conversion costs may affect the result. Transaction references and booking records should provide enough information to resolve a dispute without exposing unnecessary personal data.

Settlement can end while the relationship continues.

LGCX Passport

Current eligibility. Attributable history.

Passport is being developed as the principal interface between current asset-based eligibility and attributable participation. Its private pilot is in preparation. The interface organizes five elements. [2]

Element	Meaning
Passport ID	An application-level reference with wallet-binding and recovery rules.
Member since	The relationship's starting date, distinct from continuous token ownership.
ACTIVE NOW / INACTIVE	Qualification for a stated rule set, with a check time. Each offer retains its own conditions.
Verified Experiences	Attributable attendance or completion records; verification concerns participation, not service quality or medical efficacy.
Available Access	Opportunities with separate eligibility, availability and reservation status.

Balance and history serve different purposes

Token transfers change balances, while Member since, completed experiences and reservations remain associated with the relevant Passport relationship.

Current eligibility can change while a valid historical record remains. Data retention, correction and deletion follow the relevant privacy policy and applicable requirements. The design uses attributable records rather than an additional tradable reputation token.

Wallet binding and recovery

The intended account model centers on a primary authenticated wallet. Any additional wallet binding requires separate proof of control and an explicit association. Binding addresses is distinct from aggregating balances: an offer must specify whether additional addresses count toward eligibility.

Migration is designed to require authorization from both wallets when available. Lost-key cases need a separate recovery process with evidence, review and an auditable outcome. Passport recovery cannot recover lost or transferred tokens.

Wallet control is not unique personhood. Shared wallets, duplicates and changes of control need proportionate checks. Passport requires neither a seed phrase nor a private key.

Minimal disclosure

An eligibility check uses only the necessary LGCX state and relevant reservation or credential facts. Other tokens, NFTs, total portfolio value and medical records are outside that check. When verification is unavailable, the interface must show that condition separately from ineligibility.

The asset can provide eligibility. Only real participation can provide a history.

Passport Interoperability

From a visible record to portable evidence

Cross-provider recognition requires more than copying a profile. A receiving provider needs to understand who issued a record, what it attests, whom it concerns and whether it remains valid. The interoperability roadmap therefore targets provider-attributable credentials and verification that compatible applications can perform independently.

The issuer–holder–verifier model in the W3C Verifiable Credentials standard provides a reference for this separation. It distinguishes issuing claims, holding credentials and deciding whether to accept them. LGCX's implementation profile, proof format and status mechanism remain development specifications; conformity requires implementation and testing. [6]

Target credential flow. Issuance, presentation and acceptance carry distinct responsibilities.

Intended credential lifecycle

The issuing provider verifies attendance or completion against its own service record. A credential identifies the issuer, subject reference, activity, completion time, record identifier and schema version. Validity periods and a status or revocation reference are included where applicable. Public disclosure of those fields is not required.

For portable credentials, the issuer or an explicitly authorized issuing service signs the record. A receiving provider checks the proof, issuer authority, subject relationship, applicable validity and current status, then applies its own acceptance policy. A valid signature establishes provenance and integrity; the truth of the underlying event still depends on the issuer and its verification process.

Corrections require an attributable replacement or status change. Revocation authority and reasons must be defined. A presentation interface cannot silently rewrite an issuer's signed claim, although it can misdisplay or omit it; independent verification is intended to make that distinction inspectable.

Recognition, consent and exit

The participant chooses the relevant record or fact to present. Shared recognition rules specify which issuers and activity types are accepted, for what purpose and for how long. Clinical suitability and regulated service eligibility remain separate provider decisions.

Portable export is a development requirement. Where available, an export should retain the signed record and the information needed to verify it elsewhere. Verification may still depend on available issuer keys and status information. Copies improve continuity; they do not guarantee uninterrupted acceptance after an issuer or service disappears.

The pilot can begin with controlled application records and server-side checks. Provider-issued credentials, export, independent verification and privacy-preserving presentation are subsequent interoperability work. Each becomes available only through a corresponding tested release.

The Partner Network

Turn another institution's first encounter into a relevant next step.

The provider opportunity is not simply another payment method. It is a connection to participants whose relevant interests or prior activity can make an offer more appropriate—and whose next experience may take place elsewhere in the network.

A scientific event can introduce participants to an educational service. A digital service can help a participant discover another relevant event or provider. Where the parties publish compatible conditions, selected participation can reduce repeated qualification steps. These are intended network pathways, not a shared ownership claim over the customer relationship.

Three reasons to connect

Relevant discovery. An offer can be encountered by people already participating in a related field. Relevance should come from explicit interests and consented facts rather than hidden profiling.

Reusable qualification. A provider can accept a defined condition or completion record instead of recreating every administrative check. Its own suitability, legal and professional requirements remain in force.

Repeat and cross-provider demand. A completed encounter can create a reason to return or to use a complementary provider. The practical benefit must appear in fulfilled activity, not merely registrations or referral clicks.

The provider's economic test

The evaluation is incremental: additional service contribution and demonstrable coordination-cost savings, less integration, servicing and incentive costs. Discounts, displaced full-price bookings and support effort belong in that calculation. Token appreciation is not an operating revenue assumption.

A provider remains free to retain its own pricing, accounts and payment options. It can begin with one Access offer, eligibility check or payment route, then expand only where results justify the integration. A useful network complements the provider's existing business rather than demanding its replacement.

An accountable offer

Each offer identifies the provider and contact, deliverable, location or channel, timing, capacity, qualification rules and checkpoints, price, cancellation and refund terms, support process and necessary data. The recognition policy specifies which external records it accepts.

Participation in the network is distinct from endorsement of every provider. Service quality, professional qualifications, scientific claims and clinical decisions remain with the responsible organization. A dependable offering and a clear resolution path are the basis for continued recognition.

Network Effects

The second-provider test

A participant returning to the same provider demonstrates repeat use. A completed experience with a second independent provider tests the stronger network thesis: whether the shared asset and recognition rules help connect otherwise separate relationships.

Cross-Provider Conversion Rate is the central measure of that connection. For a stated observation window, it is defined as:

First-use participants completing activity with a second independent provider

Corresponding first-use cohort with a complete observation window

× 100%

The denominator includes first-use participants with a complete observation window; 90 days is one possible period. Those without an available second-provider opportunity remain in the headline denominator. A separate opportunity-adjusted view can explain capacity constraints.

Counted completions must be actual activity, not transfers, duplicate check-ins or unfulfilled bookings. Reporting defines provider independence, related organizations, deduplication, refunds and incentives. Wallet counts must remain distinct from verified unique people.

Measure the connection and its quality

Measure	What it tests
Cross-provider conversion	Whether first use leads to completed activity with another independent provider.
Fulfilled Access and accessible capacity	Whether relevant opportunities can actually be used.
Repeat use after incentives decline	Whether there is a reason to return beyond a reward.
Provider retention and incremental contribution	Whether participation remains worthwhile for the service side.
Cost per retained participant	Whether growth can be supported by the operating model.

Conversion indicates adoption, not causation or token necessity. Where practical, comparison with conventional booking should separate shared recognition from subsidies, marketing and service quality. Provider economics and participant satisfaction add complementary evidence.

Density before breadth

Density means relevant opportunities, reachable channels, available capacity and compatible recognition for the same participant. A useful cluster of complementary services can matter more than a geographically scattered list.

Long-term defensibility depends on dependable operations, trusted issuers, useful interfaces, repeat habits and liquidity. The shared contract supplies a reference; the network must earn the relationship.

Contracts can be copied. Network density cannot be created overnight.

Base & Technical Foundation

LGCX's canonical network is Base Mainnet: Chain ID **8453**, with **ETH** for network fees. ERC-20 defines balance, transfer and allowance interfaces. Passport, Checkout and provider processes remain separate application responsibilities. [3, 4]

Action	Technical meaning	User consequence
Read balance	Inspect the relevant token state.	No asset movement.
Sign in	Authenticate wallet control using a scoped message.	A session, distinct from payment authorization.
Approve	Grant a specified spender an allowance.	Later transfers can occur within the authorization without a fresh prompt for each transfer.
Transfer / Pay	Execute asset movement.	Check recipient, amount, network and fees.
Reserve / Check in	Verify conditions, capacity and a ticket.	Application state; separate from token settlement.

Authentication and authorization

Authentication uses explicit domains, nonces and validity periods, following Sign-In with Ethereum where appropriate. Server checks must validate the message and its context. Wallet support, session invalidation and recovery require tested implementations. [5]

A signature can authorize actions beyond login. An existing ERC-20 allowance may permit later transferFrom calls within its scope. Interfaces must distinguish reading, authenticating, approving and paying. [3]

Canonical asset and infrastructure

The canonical LGCX reference is the Base contract identified in the Protocol Snapshot. Similar names, copied symbols, wrappers and assets on other networks are not automatically equivalent. Wallets, RPC services, bridges and conversion providers have their own availability and trust boundaries.

Application displays must reconcile on-chain and service records. Outages are unavailable states, not failed eligibility tests; uncertain payments remain unconfirmed.

Technical reference and disclosures

The technical disclosure framework covers the deployment transaction and network, source-to-bytecode verification, decimals, maximum and issued supply, mint and burn authority, proxy and upgrade controls, pause or restriction functions, transfer fees, ownership and role addresses, vesting arrangements and material treasury balances.

A disclosure must distinguish code-enforced behavior from policy, include an observation date or block, and specify the scope of any third-party review. An unlisted privilege must not be assumed absent from the contract. Supply definitions and the verification boundary are set out in Section 10.

Supply

Predictable rules. Publicly inspectable state.

The published supply ceiling is **1,000,000,000 LGCX**. That ceiling is distinct from the issued supply and the amount circulating in the market. A maximum issuance bound does not, by itself, establish that the issued supply is permanently fixed. [1]

The canonical contract is the reference for supply behavior, transfer rules and technical privileges. The enforceability of the ceiling, any further issuance and the ability to change material behavior depend on deployed code and permissions—not on terminology alone.

Three quantities, three meanings

Quantity	Meaning
Maximum supply	The upper issuance bound, including whether it can be changed and by whom.
Issued supply	The outstanding supply at a stated block or time, with minting and burning treated under a disclosed method.
Circulating supply	The portion treated as available to the market under a stated methodology.

Treasury holdings, vesting balances and reserves can overlap with other categories. Explicit category definitions are used rather than adding or subtracting balances as though they were necessarily mutually exclusive.

Supply transparency

The disclosure framework covers the cap, issued supply, decimals, mint and burn permissions, upgradeability, administrative controls and the authority able to change material behavior. Code-enforced restrictions are distinguished from policy commitments.

Dated supply snapshots connect those facts with allocation categories, vesting contracts, treasury addresses and the circulation methodology. Current issued supply and the status of minting, upgrade and administrative permissions require direct contract verification; a published ceiling does not establish the absence of those powers.

Simple transfer rules

LGCX's demand model does not rely on punitive transfer taxes, reflection schemes, opaque burns or rebasing. An asset intended for real use benefits from understandable monetary and transfer rules.

Scarcity alone does not create service capacity, useful Access or a market price. It becomes economically meaningful alongside transparent rules, voluntary demand and repeat use.

A credible supply policy can be checked independently.

Distribution & Long-Term Circulation

Resource allocation for a useful network

The distribution framework is organized around the resources a long-lived network needs. Its purpose is to align ecosystem development, responsible operations and long-term circulation with work that can be inspected and used.

Category	Purpose and delivery basis
Ecosystem and merchant adoption	User participation, integrations and provider onboarding, assessed through working functionality and verified use.
Liquidity and market infrastructure	Exchange and settlement capacity, with venues, control arrangements and usable depth disclosed.
Community treasury	Development, operations, grants and projects with budgets and accountable recipients.
Core contributors	Long-term execution under defined responsibilities and release conditions.
Strategic integrations	Provider, platform and infrastructure connections that reach operational use.
Longevity public goods	Education, open tools and shared infrastructure with inspectable deliverables.
Early community	Initial participation and network formation through genuine activity.

Allocation records

Final token amounts, percentages, controlling addresses, release schedules, restrictions and responsible parties are to be published through dedicated allocation disclosures. The categories above describe allocation purposes; they do not specify a completed quantitative distribution.

Each allocation record should connect its intended use with the relevant recipient, release conditions and evidence of delivery. An integration announcement alone is insufficient to establish that an operational milestone has been met.

Release schedules use the supply definitions in Section 10. Where vesting is enforced through policy rather than code, that commitment remains distinct from an immutable lock. A locked balance must be identified together with its controller and the conditions that can change its treatment.

Continuing transparency

Material transfers, vesting changes and significant treasury decisions belong in a continuing disclosure record. Dynamic balances should be dated and linked to the appropriate address or account category.

Allocation also requires an operating discipline. Partner support, verification, security and service delivery have recurring costs. Budgets and milestone-based spending should make those costs visible and connect them to sustained use, rather than treating token issuance or distribution as a substitute for a viable service model.

Incentives, Liquidity & Velocity

From occasional payment to a useful working balance

LGCX's economic model considers five potential demand sources: transactions, Access, operations, liquidity and coordination. Their significance depends on actual use and the balance a participant voluntarily chooses to maintain.

Demand source	Practical condition
Transaction	LGCX payment is useful after acquisition and settlement costs.
Access	Relevant, available offers recognize a published LGCX condition.
Operating	Providers or applications choose to maintain working balances.
Liquidity	Market participants supply inventory under acceptable risk.
Coordination	Defined ecosystem functions require or recognize the asset.

The velocity question

A participant can acquire LGCX immediately before payment while a provider converts it immediately afterward. That creates activity without necessarily creating a continuing balance. Transaction volume and persistent demand must therefore be evaluated separately.

Access can extend the relationship where maintaining eligibility for several worthwhile opportunities is useful. The required balance, verification checkpoint and available capacity must be understandable. Passport history remains a separate participation record; withholding genuine history is not a sound mechanism for manufacturing holding demand.

Network growth and the asset

The network's development can benefit providers through service demand and participants through better opportunities. Those benefits do not automatically accrue to token holders as revenue, profit or intellectual-property rights. The economic role of LGCX depends on voluntary use of the asset's actual functions.

The relevant comparison is practical: does the shared-asset arrangement improve the experience sufficiently compared with conventional accounts and alternative payment routes? A growing longevity market alone does not answer that question.

Incentives with an exit from subsidy

Incentives are intended to support attributable participation and integration work. Their cost should be visible alongside retention, fulfilled service demand and provider economics. A useful pilot should reveal what remains after rewards decline.

Liquidity quality is measured through usable depth, concentration and execution costs at representative transaction sizes. Headline volume is not enough. Acquisition, payment and exit each depend on the market conditions at the time.

Sustained demand must rest on opportunities that remain worth using. Yield is not the default retention mechanism.

Governance, Treasury & Stewardship

Responsibility that can be identified

Governance expands with network maturity. The intended progression is accountable stewardship, community signaling, limited on-chain functions and broader network governance where operational and legal conditions support it.

Stage	Scope
I · Stewardship	Operation of interfaces, provider processes, documentation and incident response by identifiable responsible parties.
II · Community signaling	Non-binding input on integrations, priorities, grants and public goods.
III · Limited on-chain governance	Specifically defined functions suited to transparent automation.
IV · Network governance	Broader participation after authority, safeguards and maintenance responsibilities are established.

Who is responsible for what?

Application operators are responsible for the interfaces, sessions, support and operational records they control. **Providers** are responsible for their offers, service delivery and attestations. **Treasury decision-makers** are responsible for approved expenditure and disclosure. **Participants** retain control of their wallets and authorize the information they share.

These roles are not interchangeable. Each operating service must identify the actual responsible entity and contact in its terms. The existence of a transferable token does not make every surrounding process decentralized.

Treasury and public goods

Treasury priorities are development, security, integration, user support, liquidity infrastructure and public goods. Material expenditure should identify its purpose, decision-maker, recipient and delivery conditions. Integration support is intended to establish useful capability, while public-goods funding supports resources that participants and independent builders can use.

The treasury control framework calls for multi-party authorization, separation of duties and delays for material changes where feasible. Applicable authorities and active safeguards are to be documented with the relevant control addresses and policies.

Transparency Registry

A planned Transparency Registry will organize the canonical contract, operator identity and contact, material addresses, dated supply and distribution records, treasury policies, audit scope, incidents and product availability. It should distinguish verified records, published commitments and functions still in development.

Holding LGCX does not create a general authority over providers. Clinical decisions, private medical data and responsibilities reserved to regulated professionals or accountable entities remain outside token voting. Any future governance function requires an explicit scope and implementation.

Privacy & Data Boundaries

Passport centers privacy on data minimization and participant-directed disclosure. Public-chain addresses, balances and transfers remain observable and potentially identifiable. Participation records must avoid unnecessary additional exposure.

Boundary	Treatment
Public chain	Balances, transfers and events; no medical results or detailed experience history required.
Passport and applications	Minimum session, eligibility, reservation and verification facts.
Provider systems	Service and legally required records under provider responsibility.
Outside Passport's role	Genomes, methylation profiles, biological-age scores, diagnostic results and medical records.

A provider, location or activity time can reveal sensitive information. Participation metadata therefore needs restricted visibility, explicit sharing, retention limits and correction procedures. Selective credentials and stronger privacy-preserving presentation remain development directions, not anonymity claims. [6]

15 / Security & Trust Model

Security covers the asset, network infrastructure, wallets, applications and providers. Each boundary needs its own controls and incident responsibility.

Exposure	Design requirement
Contract and spending permissions	Inspectable authority, clear transaction previews and bounded approvals.
Sessions and tickets	Scoped authentication, server verification, replay protection and one-time redemption.
Reservations and completion	Atomic capacity checks, attributable records, corrections and audit trails.
Provider or issuer failure	Identity and authority checks, defined status handling, support and incident response.
Infrastructure outage	Explicit unavailable or uncertain states rather than false failure or success.

Self-custody protects the custody boundary, not every interaction. Stolen keys, malicious approvals or compromised interfaces can still cause loss. Passport recovery concerns the account relationship; it cannot reverse a token transfer.

Audit disclosures must identify the auditor, code version, scope, date and unresolved findings. Token audits cover Passport or provider operations only if explicitly included. Incident procedures identify affected functions, contacts and recovery steps. An application suspension differs from a token freeze, which depends on actual contract powers.

Regulatory Posture

LGCX's legal treatment depends on its rights, distribution, operation and the jurisdictions involved. A label such as “utility token” does not resolve classification. Where MiCA applies, the relevant requirements address whitepaper information and marketing communications, including clarity, material omissions and statements about future value. [7, 8]

Holding LGCX does not, by itself, confer equity, a claim on provider revenue, dividends, biotechnology intellectual property or fixed-value redemption. The name does not designate legal tender, a stablecoin or a bank deposit. Access follows provider terms, capacity and applicable eligibility requirements.

A verified participation record establishes an attendance or completion claim. Professional qualifications, scientific substantiation, informed consent and clinical suitability remain provider responsibilities. LGCX recognition is separate from a medical endorsement or guaranteed access to treatment or a clinical trial.

Regulated activities require the relevant responsible entities, authorizations and disclosures. This whitepaper does not constitute regulatory approval or replace those requirements.

17 / What Comes Next

Asset. Network. Protocol.

Development proceeds through three stages. The baseline product status is a private Passport pilot in preparation as of **6 September 2026**. Progress is measured by completed use and operational reliability. [1, 2]

Stage	Deliverable	Progression evidence
I · Asset + Access	A focused Passport pilot, accountable offers and reservation / verification flows.	Clear terms, adequate capacity, working support and completed experiences.
II · Network	Additional independent providers, discovery, settlement routes and selected recognition.	Cross-provider conversion, dependable fulfillment and sustainable provider economics.
III · Protocol	Documented interfaces, portable provider credentials, export and independent verification.	A working independent integration, tested recovery and privacy boundaries, clear maintenance responsibility.

Scientific, educational and community experiences are the initial operating focus. Clinical integration requires additional provider-specific controls. Credential interoperability, stronger privacy mechanisms and broader governance are development targets requiring separate implementation and testing.

Public availability uses five states: **planned, pilot, live, paused and retired**. A live service requires an accessible function, published terms and an identifiable responsible party. Partner agreements and development milestones are reported separately from available capacity and actual completed use.

Risks

LGCX may lose some or all of its market value. A useful design, a deployed token or a growing community does not guarantee adoption, liquidity, service availability or financial return.

Risk	Possible consequence
Price and liquidity	Extreme volatility, insufficient market depth, high execution costs or inability to sell when desired.
Supply and concentration	Further issuance, reserve releases, concentrated control or poorly understood privileges can materially affect market conditions.
Adoption and execution	Passport, integrations and cross-provider recognition may remain limited or never become available.
Token relevance	Providers and participants may prefer conventional accounts or other assets even if longevity services grow.
Smart contracts and permissions	Bugs, administrative abuse, malicious approvals or compromised infrastructure may cause asset loss.
Network and wallets	Outages, bridge failure, lost keys, incorrect addresses or phishing may cause interruption or irreversible loss.
Service and issuer conduct	An offer may fail; a provider may misstate completion, issue an incorrect credential or become unavailable. Recognition does not establish clinical quality.
Privacy and continuity	Transaction links and activity metadata may disclose identity or sensitive information. Recovery, export, status checks and future acceptance may fail.
Treasury and governance	Compromised keys, opaque spending, conflicts or concentrated authority may impair the network.
Law and operating costs	Restrictions, regulatory change or unsustainable costs may limit operation and participation.

Rights and limitations

A balance does not guarantee an event place, booking, provider's continued participation or permanent eligibility. A reserved or paid commitment is governed by the relevant terms and applicable law. Future interoperability cannot compel another provider to accept a record.

LGCX offers no guaranteed yield, appreciation, exchange listing, medical benefit or life extension. No general right to dividends, biotechnology ownership or fixed-value redemption is established by this paper.

The roadmap depends on development, integration and delivery. Contract controls and supply behavior require the verification described in Section 10. Completed audits and available services must be established through specific disclosures, not inferred from the existence of the token.

Time

A network worth returning to.

Longevity discussions often jump directly to the most dramatic endpoint: how many additional years might eventually become possible. Real markets usually form more quietly. First a test, then a retest; first a new service, then a longer relationship; first a payment, then a second use that feels more natural.

LGCX is built around the possibility that these encounters can connect. One provider need not become the whole world. One application need not own the relationship. Assets can remain under their holder's control while relevant participation becomes easier to recognize elsewhere.

The long horizon has room for scientists, builders, providers and participants who approach it from different directions. Their common ground is an interest in what can become possible when health, knowledge and continuity receive sustained attention. Belonging acquires substance through useful work and experiences that can be trusted.

A practical invitation

For a participant, begin with an opportunity that matters. Read its terms, understand what is available and use an amount appropriate to its purpose and risks. Let the experience determine whether the next step is worthwhile.

For a provider, open something useful, deliver it reliably and examine whether shared recognition improves the next relationship. For a builder, the opportunity is to make those connections easier to understand and safer to use.

LGCX's ambition is for those steps to add up to a network rather than remain isolated transactions: an asset that can move, a history that can carry forward and independent institutions with a reason to recognize both.

Traditional money records exchange. LGCX seeks to build an economic layer around an older and more universal aspiration: to live longer, better and more freely.

Time remains scarce. The economic layer forming around it is only beginning.

LGCX — FOR THE LONG HORIZON

A /

Protocol Principles

Participant control. Self-custody, understandable authorizations and deliberate information sharing.

Independent providers. Shared recognition with local responsibility for services, pricing and delivery.

Distinct states. Transferable balances, attributable participation, eligibility, reservations and payments each retain their own meaning.

Verifiable operation. Inspectable asset information, identifiable issuers and accountable public records.

Useful participation. Real capacity, fulfilled offers and repeated use are the basis for expansion.

Sustainable coordination. Incentives and governance support work that remains worthwhile beyond perpetual subsidy.

B / Glossary

Term	Meaning
Economic state	LGCX balances and transfers, read from the relevant on-chain state.
Participation state	Attributable relationship and activity records, distinct from balances.
LGCX Access	Provider-defined eligibility for a published opportunity; distinct from reserving or paying for it.
Verified Experiences	Passport's verified participation records: evidence of attendance or completion, not verified medical efficacy.
Member since	The beginning of a Passport relationship, not continuous asset ownership.
Portable credential	An issuer-attributable record intended for presentation and verification in compatible applications.
Recognition policy	The receiving provider's accepted issuers, record types, purposes and validity conditions.
Utility density	The relevant, usable opportunities a participant can actually reach.
Cross-Provider Conversion Rate	First-use participants completing activity with a second independent provider within a disclosed window, divided by the corresponding fully observed first-use cohort.
Transparency Registry	The planned continuing record of canonical facts, responsibility, treasury, security and product status.
